#### 1.1 Assignment Submission

1 Assignment Policies

Gather all the python source files within the taichi\_tracer/ folder (i.e., everything except the scene\_data\_dir/

All future assignments, including this one, will build on top of Assignment 1.

## YourStudentID.zip

For example, if your ID is 234567890, your submission filename should be 234567890.zip. DO NOT ADD ANYTHING BEFORE OR AFTER THE MCGILL ID.

folder) and compress them into a single zip file. Name your zip file according to your student ID, as:

#### Every time you submit a new file on *myCourses*, your previous submission will be overwritten. We will only grade the **final submitted file**, so feel free to submit often as you progress through the assignment.

1.2 Late policy

In accordance with article 15 of the Charter of Students' Rights, students may submit any written or programming components in either French or English.

All the assignments are to completed individually. You are expected to respect the late day policy and collaboration/plagiarism polices, discussed below.

Late Day Allotment and Late Policy Every student will be allowed a total of **six (6)** late days during the entire semester, without penalty.

If you require an accomodation, please advise McGill Student Accessibility and Achievement (514-398-6009) as early in the semester as possible. In the event of circumstances beyond our control, the evaluation scheme as detailed on the course website and on assignment handouts may require modification.

## 1.3 Collaboration & Plagiarism

You are expected to submit your own work. Assignments are individual tasks. This does not need to preclude forming an environment where you can be comfortable discussing ideas with your classmates. When in doubt, some good rules to follow include: fully understand every step of every solution you submit,

Plagiarism is an academic offense of misrepresenting authorship. This can result in penalties up to expulsion. It is also possible to plagiarise your own work, e.g., by submitting work from another course without proper attribution.

• never refer to another student's code — if at all possible, we recommend that you avoid looking at another classmates code. McGill values academic integrity and students should take the time to fully understand the meaning and consequences of cheating, plagiarism and other academic offenses (as defined in the Code of Student Conduct and

Computational plagiarism detection tools are employed as part of the evaluation procedure in ECSE

Additional policies governing academic issues which affect students can be found in the Handbook on Student

Rights and Responsibilities.

rather than environmental emitters, to light our scene.

**BRDF Importance Sampling** 

Recall the formula for this MC estimator:

**BRDF Sampling @ 1 SPP** 

sampling.

sampling, you can just call your previous method.

1. first, you must choose an emissive triangle from your mesh by sampling

surface area of the (marginally) sampled triangle according to the

so, build a (1D) cumulative distribution function over all emissive triangle areas, and perform inversion sampling using 1D binary search over the (inverted) CDF, using a canonical uniform variate  $\xi_{\text{triangle}} \in [0, 1]$ ; and,

2. after choosing your emissive triangle (i.e., sampling a triangle i proportional to

the marginal density  $i \sim p_{\text{triangle}}$ ), you can sample a point uniformly over the

according to a probability distribution function  $p_{\text{triangles}}(t)$  over triangles; to do

Mesh Lights

The most notable change from the previous assignment is the inclusion of mesh lights,

446/546. Students may only be notified of potential infractions at the end of the semester.

emissivity associated to their material property Material.Ke. Mesh Lights.

You will begin by modifying your BRDF Importance Sampling direct illumination estimator to support mesh lights.

**BRDF Sampling @ 10 SPP** 

Modify your A2Renderer's render() routine to support mesh lights with BRDF importance

Your A3Renderer instantiates an A2Renderer object. You do not need to re-implement BRDF importance

# $L_o(\mathbf{x}, \boldsymbol{\omega}_o) \approx \frac{1}{N} \sum_{i=1}^{N} \frac{L_e(\mathbf{x}, \boldsymbol{\omega}_j) V(\mathbf{x}, \boldsymbol{\omega}_j) f_r(\mathbf{x}, \boldsymbol{\omega}_o, \boldsymbol{\omega}_j) \max(\mathbf{n} \cdot \boldsymbol{\omega}_j, 0)}{p_{brdf}(\boldsymbol{\omega}_j)},$

**BRDF Sampling @ 100 SPP** 

## where you previously evaluated $L_e(\mathbf{x}, \boldsymbol{\omega})$ as (spatially-invariant) environment map emission $L_{env}(\boldsymbol{\omega})$ .

**Deliverable 1** [10 points]

**Light Importance Sampling** 

(conditional) density p(y|i):

emissive

on the

Mesh Light Importance Sampled  $\omega_{\mathbf{i}}$ 

The probability of your sample is the product of the marginal probability of choosing the emissive triangle from the mesh light  $p_{\text{triangle}}$  propotional to its area, times the conditional probability  $p(\mathbf{y}|t)$  of sampling a point uniformly on

direction  $\omega_i$  but also the ID of your sampled emissive triangle.

Implement the sampled\_mesh\_lights() function in MeshLightSampler, which returns both a

 $\frac{1}{n_f} \sum_{i=1}^{n_f} \frac{f(x_j) \, w_f(x_j)}{p_f(x_j)} + \frac{1}{n_g} \sum_{k=1}^{n_g} \frac{f(x_k) \, w_g(x_k)}{p_g(x_k)},$ where  $n_f$  and  $n_g$  are the number of samples ( $x_j \sim p_f$  and  $x_k \sim p_g$ ) drawn from the  $p_f$  and  $p_g$  distributions, and  $w_f$  and  $w_g$  are special weighing functions chosen so that the expectation of the estimator is the desired integral F. One provably good choice of weighing functions follows the balance heuristic:  $w_s(x) = \frac{n_s p_s(x)}{\sum_{i \in S} n_i p_i(x)},$ where  $s \in S = \{f, g\}$ , in our two-strategy setting, above. While this general MIS formulation is suitable, in the context of our 1-sample per-render-iteration progressive rendering setting, it poses a problem: with the smallest setting of  $n_f = n_g = 1$ , each iteration will generate two samples.

Since we absolutely wish to maintain the 1-sample-per-pass property instead, we can exploit an important property of the balance heuristic: when using an equal number of samples per strategy, samples drawn in the MIS estimator

In other words, in our two-strategy setting, if you draw samples  $\omega_i$  according to the average of the light and BRDF

 $L_o(\mathbf{x}, \omega_o) \approx \frac{1}{N} \sum_{i=1}^{N} \frac{L_e(\mathbf{x}, \omega_i) V(\mathbf{x}, \omega_i) f_r(\mathbf{x}, \omega_o, \omega_i) \max(\mathbf{n} \cdot \omega_i, 0)}{p_{mis}(\omega_i)},$ 

then your estimator will be statistically equivalent to the more general MIS-with-balance-heuristic estimator above, in the  $w_{brdf} = 1/2$  and  $w_{light} = 1/2$  setting. More generally, for weighins that favour one of the strategies more than the other (i.e., where  $w_{brdf} \neq w_{light}$ ), you can employ the 1-sample strategy discussed during during the lectures, where you first stochastically choose a strategy and then sample according to it (with an appropriate 1-sample MIS weight). In these cases, you can explore the design space of trade-offs between pure-BRDF vs. pure-Light

 $w_{brdf} = \frac{1}{2}, w_{light} = \frac{1}{2}$ 

 $w_{brdf} = \frac{1}{4}, w_{light} = \frac{3}{4}$ 

with the balance heuristic weights are — in aggregate — proportional to the average of all the strategies.

PDFs,  $\omega_j \sim p_{mis}(\omega) = \frac{p_{light}(\omega)}{2} + \frac{p_{brdf}(\omega)}{2}$  and use them in a standard MC estimator, as

Importance Sampling, and every combined strategy in between them (as illustrated, below).

 $w_{brdf} = \frac{3}{4}, w_{light} = \frac{1}{4}$ 

 $10^{2}$ SPP

Deliverable 3 [10 points]

into a renderer to those interested students.

sampling procedure, as discussed in class:

• Step 1: Initializing the joint probabilty distribution  $p(\phi, \theta)$ 

distribution  $p(\phi, \theta)$  we will aim to importance sample:

• Step 2: Precomputing the marginal probabilty distribution  $p(\theta)$ 

by summing and normalizing over each row of your joint distribution.

Recall that, given two sampling distributions  $p_f$  and  $p_g$  used to estimate an integral  $F = \int f(x) dx$ , we can express

**ECSE 546 Students Only** 6 Environment Light Importance Sampling

estimate that combines BRDF and Light sampling distributions.

**Uniform Samples** 

Implement the precompute\_marginal\_ptheta() function in the Environment class to precompute

• Implement the sample\_theta() and sample\_phi() functions in the Environment class which will sample a  $\phi$  and  $\theta$  using inversion sampling of the CDFs • Implement the importance\_sample\_envmap() function in the Environment class which will return a normalized [u,v] texture coordinate for your sample on the environment map's latitude-longitude coordinate system

start of this handout before submitting your assignment solution.

Since you are sampling from a discretized CDF, when computing the normalized [u, v] coordinates, you will need to linearly interpolate (i.e., using a lerp()) the  $\theta$  and  $\phi$  values that you sampled.

Congratulations, you've completed the 3<sup>rd</sup> assignment. Review the submission procedures and guidelines at the

treated as per McGill's Policies on Student Rights and Responsibilities.

Specifically, failure to submit a (valid) assignment on time will result in a late day (rounded up to the nearest day) being deducted from the student's late day allotment. Once the late day allotment is exhausted, any further late submissions will obtain a score of 0%. Exceptional circumstances will be

only submit solution code that was written (not copy/pasted/modified, not ChatGPT'ed, etc.) by you, and

Disciplinary Procedures — see these two links).

When in doubt, attribute!

Mesh lights are treated as "first-class" physical objects in the scene, meaning they are associated with scene geometry (just like every other non-emitting object) and with

With mesh lights, however, you will now need to check if your shadow rays intersects an emissive object when evaluating V and  $L_e$ . Concretely, your visibility check  $V(\mathbf{x}, \boldsymbol{\omega})$  now checks for a successful hit with an emissive object, rather than a miss (i.e., an environmental "hit").

The next Monte Carlo estimator that you will implement is one that conducts mesh light importance sampling. To do so, we will proceed in two steps:

 $\circ$  with the third barycentric coordinate as  $b_2 = 1 - b_0 - b_1$ , you arrive at the sampled surface point on the mesh  $\mathbf{y} = b_0 \mathbf{v}_0 + b_1 \mathbf{v}_1 + b_2 \mathbf{v}_2$ , where  $\mathbf{v}_0, \mathbf{v}_1, \mathbf{v}_2$  are triangle *i*'s vertices.

 $\circ$  given canonical uniform random variates  $\xi_0, \xi_1 \in [0,1]$ , compute barycentric coordinates  $b_0$  and  $b_1$  as

if  $\xi_0 < \xi_1$ :  $b_0 = \frac{\xi_0}{2}$  and  $b_1 = \xi_1 - b_0$ otherwise:  $b_1 = \frac{\xi_1}{2}$  and  $b_0 = \xi_0 - b_1$ 

where  $A_i$  denotes the area of a triangle i and t is the index of the sampled triangle. The light importance sampled Monte Carlo estimator is thus:  $L_o(\mathbf{x}, \boldsymbol{\omega}_o) \approx \frac{1}{N} \sum_{j=1}^{N} \frac{L_e(\mathbf{x}, \boldsymbol{\omega}_j) \ V(\mathbf{x}, \boldsymbol{\omega}_j) \ f_r(\mathbf{x}, \boldsymbol{\omega}_o, \boldsymbol{\omega}_j) \ \max(\mathbf{n}_{\mathbf{x}} \cdot \boldsymbol{\omega}_j, 0) \ \max(\mathbf{n}_{\mathbf{y}_j} \cdot -\boldsymbol{\omega}_j, 0)}{p_{\text{light}}(\mathbf{y}_j) \ ||\mathbf{x} - \mathbf{y}_j||^2}$ where  $\omega_j = (\mathbf{y}_j - \mathbf{x})/||(\mathbf{y}_j - \mathbf{x})||$  and the integration points  $\mathbf{y}_j \sim p_{\text{light}}$  are drawn over emissive surfaces. **Light Sampling @ 10 SPP Light Sampling @ 1 SPP Light Sampling @ 100 SPP** 

 You will need the ID of the sampled emissive triangle during your visibily check. • You do not need to implement every helper function as described: these helpers are put in place to help guide you towards the solution; you can feel free to implement the entirety of this deliverable as you see fit. Taichi loops are highly optimized, and are not guaranteed to run in sequential order. In fact, they almost never will. If you want to perform an operation that requires specific sequential processing (e.g., computing a CDF), you can force taichi to run a specific loop in "serialized" mode, which will force the order of operations to be respected, by decorating the loop as follows: ti.loop\_config(serialize=True) for i in range(emissive\_triangles): sum += pdf[i] cdf[i] = sumThis obviously runs slower than a regular loop, however this is the only way to guarantee a sequential operation. You will need to be mindful of taichi's optimization when performing certain tasks in this assignment.

SPP 10 SPP

Update your A3Renderer's render() routine to support (1-sample) MC estimation with an MIS

The final deliverable (for ECSE 546 students) for this assignment will be environment light importance sampling. Rather than rendering a scene directly, we will in the environment map space to validate that our importance sampling routine generates appropriate sampling distributions — we leave the exercise of integrating these samples

To perform our experiments, we provide you with a custom visualization pipeline, EnvISRenderer. This visualizer samples points on the environment map, and displays a normalized distribution of your points on a latitude-longitude

In order to importance sample an enivronment map, you will need to implement the following marginal-conditional

The first step is to convert the RGB environment map into a scalar luminance map. There are many ways to do

Luminance(RGB) = 0.2126R + 0.7152G + 0.0722B.

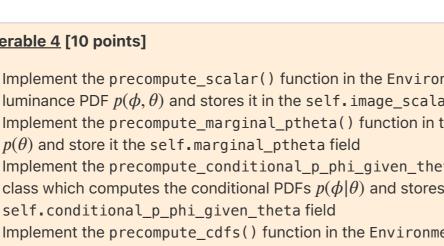

Once you have your luminance map, you then need to scale it by  $\sin(\theta)$  to arrive at the joint probabilty

 $p(\phi, \theta) = \text{Luminance}(L_{env}(\phi, \theta)) \sin(\theta)$ 

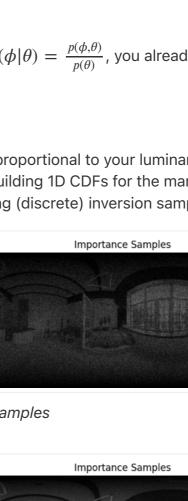

Next, we need to compute and store the marginal distribution  $p(\theta)=\int_0^{2\pi}p(\phi,\theta)d\phi$ , which you can generate

so (e.g., max or average RGB value) but we will perform the following **luminance** conversion:

Step 3: Conditional probability distribution  $p(\phi|\theta)$ When it comes time to evaluate the 1D conditional probability distribution  $p(\phi|\theta)=rac{p(\phi,\theta)}{p(\theta)}$ , you already have the joint and marginal PDFs at your disposal. • Step 4: The final step is to actually perform the (importance) sampling! To sample proportional to your luminance map, first sample a  $\theta_i \sim p(\theta)$  and then sample  $\phi_i \sim p(\phi|\theta_i)$ . You'll do this by building 1D CDFs for the marginal (one)  $p(\theta)$  and (many) conditional  $p(\phi|\theta)$  PDFs, and then sample them using (discrete) inversion sampling. Importance Samples **Uniform Samples** Importance Sampled Environment Map @ 1 Million Samples **Uniform Samples** Importance Samples

Importance Sampled Environment Map @ 10 Million Samples Importance Samples Importance Sampled Environment Map @ 100 Million Samples **Deliverable 4** [10 points] • Implement the precompute scalar() function in the Environment class which computes the luminance PDF  $p(\phi, \theta)$  and stores it in the self.image scalar field
